### Exp: 1D Columnar Transposition Techniques

Date: 24-02-2024

#### Aim:

To write a python program implementing columnar transposition techniques.

### **Algorithm:**

- 1. The message is written out in rows of a fixed length, and then read out again column by column, and the columns are chosen in some scrambled order.
- 2. Width of the rows and the permutation of the columns are usually defined by a keyword.
- 3. The permutation is defined by the alphabetical order of the letters in the keyword.
- 4. Any spare spaces are filled with nulls or left blank or placed by a character (Example: \_).
- 5. Finally, the message is printed off in columns, in the order specified by the keyword.

## Program:

```
import math
def encryptMessage(msg,key):
      cipher = ""
      k indx = 0
      msg len = float(len(msg))
      msg lst = list(msg)
      key lst = sorted(list(key))
      col = len(key)
      row = int(math.ceil(msg len / col))
      fill null = int((row * col) - msg len)
      msg lst.extend(' '* fill null)
      matrix = [msg_lst[i: i + col]
                   for i in range(0, len(msg_lst), col)]
      for _ in range(col):
             curr idx = key.index(key lst[k indx])
             cipher += ".join([row[curr idx]
                                       for row in matrix])
```

```
k indx += 1
      return cipher
def decryptMessage(cipher,key):
      msg = ""
      k indx = 0
      msg indx = 0
      msg len = float(len(cipher))
      msg_lst = list(cipher)
      col = len(key)
      row = int(math.ceil(msg_len / col))
      key_lst = sorted(list(key))
      dec cipher = []
      for in range(row):
            dec cipher += [[None] * col]
      for _ in range(col):
            curr idx = key.index(key lst[k indx])
            for j in range(row):
                   dec_cipher[j][curr_idx] = msg_lst[msg_indx]
                   msg indx += 1
            k indx += 1
      try:
            msg = ".join(sum(dec_cipher, []))
      except TypeError:
            raise TypeError("This program cannot",
                                      "handle repeating words.")
      null_count = msg.count('_')
      if null count > 0:
            return msg[: -null count]
      return msg
msg = input()
key=input()
cipher = encryptMessage(msg,key)
print("Encrypted Message: {}".
                  format(cipher))
print("Decrypted Message: {}".
      format(decryptMessage(cipher,key)))
```

# **Output:**

```
(kali® kali)-[~]
$ vi railfence.py

(kali® kali)-[~]
$ python3 railfence.py
Always be happy
sruthi
Encrypted Message: yh_sa_lbpA pa _wey
Decrypted Message: Always be happy
(kali® kali)-[~]
```

### Result:

Thus the python program for columnar transposition techniques is implemented successfully.
